

Abstract of the Disclosure

5 A generally horizontally sliding door includes a sliding or otherwise
translating door panel with a full-perimeter seal that engages sealing surfaces upon
closing and at least partially disengages the surfaces upon opening. The door panel
travels along an overhead track that is slightly inclined to lower the panel's upper and
lower edge seals into engagement with sealing surfaces as the door closes. To provide
a substantially full-perimeter seal, a leading edge seal and a trailing edge seal engage
10 sealing surfaces as well. Some of the edge seals are joined to create corner seals. The
seals are adapted for single panel sliding doors, bi-parting doors, multi-panel doors,
and various combinations thereof.
